In the context of a discussion of the (much-debated) question of the form of the continuous normal distribution, the following vague claim is sometimes (or sometimes only?) made. The normal distribution has probability density function $f(x) = \frac{\varphi(x)}{\sqrt{2\pi}}$, where $\varphi(x) = \int_{-\infty}^x e^{-y^2/2} dy$. In the text of some works on statistics (e.g., [1]) it is claimed that this is wrong, and that it is the function $\phi(x) = \int_{-\infty}^x e^{-y^2/2} dy$, and not f , that is the normal distribution. For example, Hillari and Salopek argue as follows [3]. Most people have been taught that the normal distribution is symmetrical around 0 . However, the probability density function is very asymmetrical: this is something which is much harder to see. The reason it is so hard to see is that the density function is always positive, not only positive on the real line. Because it is so asymmetrical, the maximum deviation $\Delta(x) = \text{sup}_{-\infty} f(x)$
